

Computational sociophonetics using automatic speech recognition

Algorithms Used	Advantages	Disadvantages	Limitations	Results	Conclusion
Automatic Speech Recognition (ASR)				Differences between Standard and Southern American English in the automatic transcription; Replicated experiment with newer ASR algorithms and observed both Southern and Inland North sociolinguistic phenomena in the uncorrected data.	Outlined the process of accelerating sociolinguistic research with the assistance of algorithms (e.g. forced alignment, automated speech recognition), and potential pitfalls, such as biases in how the data is gathered.
Forced Alignment	Leverage the ubiquity of [Voice over Internet Protocol] technology.				
Deep-learning based systems		One drawback of deep-learning is these algorithms need massive amounts of data for successful training.		Drastically improve transcription results.
